

# Cpt S 422: Software Engineering Principles II

## White-box testing

---

Dr. Venera Arnaoudova

# Outline

---

- ❑ Control flow coverage
  - Statement, Edge, Condition, Path coverage
- ❑ Data flow coverage
  - Definitions-Usages of data
- ❑ Analyzing coverage data
- ❑ Integration testing
  - Coupling-based criteria
- ❑ Conclusions
  - Generating test data, Marick's Recommendations

# Control Flow Graph (CFG) - Basic Definitions

---

- ❑ Directed graph
- ❑ Nodes are blocks of sequential statements
- ❑ Edges are transfers of control
- ❑ Edges may be labeled with predicate representing the condition of control transfer
- ❑ Directed Graphs can also be represented with an adjacency matrix

# Basics of CFG

## If-Then-Else

```
1 If <condition>
2   Then
3     <then statements>
4   Else
5     <else statements>
6 End If
7 <next statement>
```

## Pretest loop

```
1 While <condition>
2   <repeated body>
3 End While
4 <next statement>
```

## Case/Switch

```
1 Case n of 3
2   n=1:
3     <case 1 statements>
4   n=2:
5     <case 2 statements>
6   n=3:
7     <case 3 statements>
8 End Case
```

## Posttest loop

```
1 Do
2   <repeated body>
3 Until <condition>
4 <next statement>
```

Note that some of those nodes can be grouped

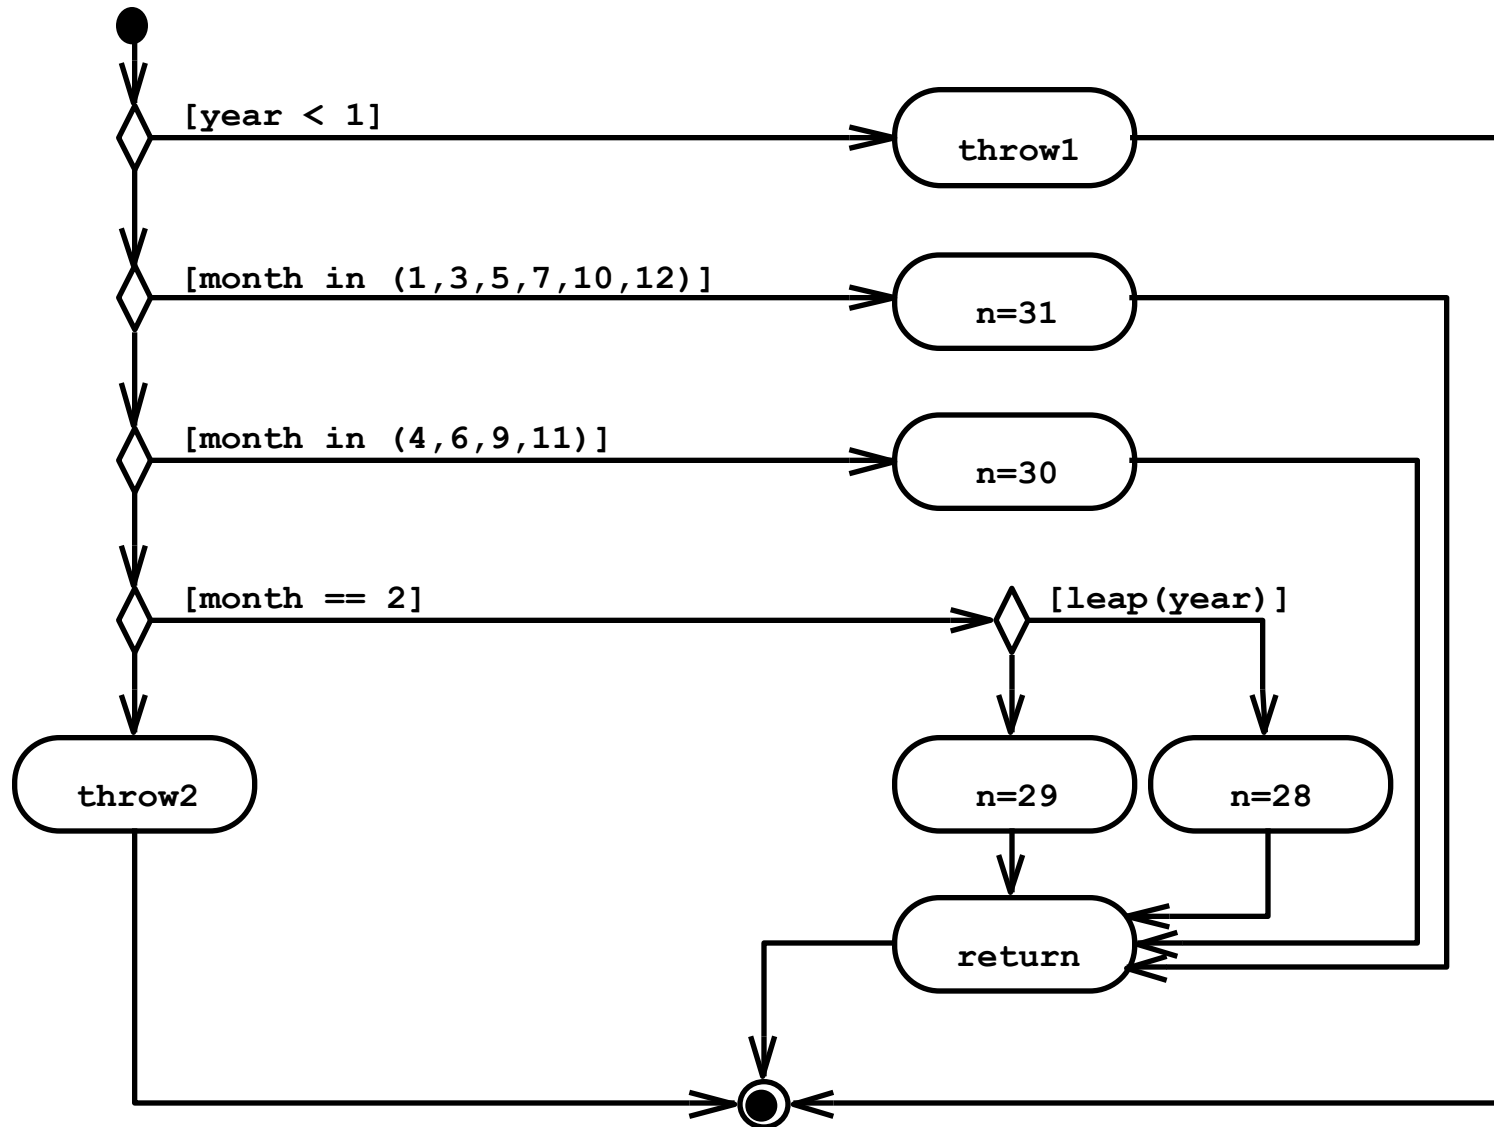

# CFG - Example

---

```
1: read(x);  
2: read(y);  
3: while  $x \neq y$  loop  
4:   if  $x > y$  then  
5:      $x := x - y;$   
6:   else  
7:      $y := y - x;$   
8:   end if;  
9: end loop;  
10:  $\text{gcd} := x;$ 
```

# UML Activity Diagram

# Statement/Node Coverage

---

- ❑ Statement coverage: faults cannot be discovered if the parts containing them are not executed
- ❑ Equivalent to covering all nodes in CFG
- ❑ Executing a statement is a weak guarantee of correctness, but easy to achieve
- ❑ In practice, several inputs will execute the same statements

# Statement coverage - Incompleteness

---

- Statement coverage may lead to incompleteness

```
if x < 0 then  
    x := -x;  
end if  
z := x;
```

A negative x would result in the coverage of all statements.

But not exercising  $x \geq 0$  would not cover all cases.

The program behavior for  $x \geq 0$  may turn out to be wrong and need to be tested.

# Edge Coverage

---

- ❑ **Edge (branch) coverage criterion:** Select a test set  $T$  such that, by executing  $P$  for each  $t$  in  $T$ , each edge of  $P$ 's control flow graph is traversed at least once
- ❑ Exercise all conditions that govern control flow of the program with true and false values
- ❑ To satisfy the edge coverage criterion for the example on the previous slide we would need to have a test with  $x < 0$  and a test with  $x \geq 0$

# Another Example - Search Algorithm

---

```
counter := 0;
found := false;
if number_of_items  $\neq$  0 then counter := 1;
    while (not found) and counter  $<$  number_of_items loop
        if elementAt(counter) = desired_element then
            found := true;
        end if;
        counter := counter + 1;
    end loop;
end if;
if found then write ("the desired element exists");
else write ("the desired element does not exists");
end if;
```

☐ Provide a test set to satisfies the Edge Coverage criterion

# Test Set

---

- ❑ We can choose a test set as follows ( $|T| = 2$ ):
  - t1: A collection with 0 items
  - t2: A collection with 3 items, the second being the desired one
- ❑ With t1, we cover the else statements of the first and last ifs
- ❑ With t2, the body of loop is executed twice, once executing the **then** branch and finding the element.
- ❑ The edge coverage criterion is fulfilled but the error is not discovered by the test set as not all possible values of the *constituents* of the **while loop** condition have been exercised

# Condition Coverage

---

- ❑ Further strengthen edge coverage
- ❑ **Condition Coverage Criterion:** Select a test set  $T$  such that, by executing  $P$  for each element in  $T$ , each edge of  $P$ 's control flow graph is traversed, and all possible values of the constituents of compound conditions are exercised at least once
- ❑ **Compound conditions:**  $C1$  and  $C2$  or  $C3 \dots$  where  $C_i$ 's are relational expressions or boolean variables (atomic conditions)
- ❑ **Modified Condition Decision Coverage (MCDC):** Only combinations of values such that every  $C_i$  drives the overall condition truth value twice (true and false). (Almost identical to ACC)

# Uncovering Hidden Edges

---

```
if c1 and c2 then
    st;
else
    sf;
end if;
```

```
if c1 then
    if c2 then
        st;
    else
        sf;
    end if;
else
    sf;
end if;
```

- ❑ Two equivalent programs but chances are that you would write the left one
- ❑ Edge coverage
  - would not compulsorily cover the “hidden” edges,
  - Ex.: C2 = false might not be covered
- ❑ Condition coverage would!

# MCDC - Example

---

- ❑ International Standard DO-178B for airborne systems certification (1992)
- ❑ Example :  $A \wedge (B \vee C)$

	ABC	Result
1	TTT	T
2	TTF	T
3	TFT	T
4	TFF	F
5	FTT	F
6	FTF	F
7	FFT	F
8	FFF	F

Pairs of points where each constituent is toggled and the change is visible in the outcome:

- A : (1,5), or (2,6), or (3,7)
- B : (2,4)
- C : (3,4)

Minimal set to satisfy MCDC:

- (2,3,4,6) or (2,3,4,7)

That is 4 test cases (instead of 8 for all possible combinations)

# Path Coverage

---

- ❑ **Path Coverage Criterion:** Select a test  $T$  such that, by executing  $P$  for each  $t$  in  $T$ , all paths leading from the initial to the final node of  $P$ 's control flow graph are traversed
- ❑ In practice, however, the number of paths is too large, if not infinite
- ❑ Some paths are infeasible
- ❑ It is key to determine “critical paths”

# Example

---

```
if x  $\neq$  0 then  
    y := 5;  
else  
    z := z - x;  
end if;  
if z > 1 then  
    z := z / x;  
else  
    z := 0;  
end if;
```

$T1 = \{ \langle x=0, z=1 \rangle, \langle x=1, z=3 \rangle \}$ :

Executes all edges but do not show risk of division by 0

$T2 = \{ \langle x=0, z=3 \rangle, \langle x=1, z=1 \rangle \}$ :

Would find the problem

$T1 \cup T2$ :

All paths are covered

# Dealing with Loops

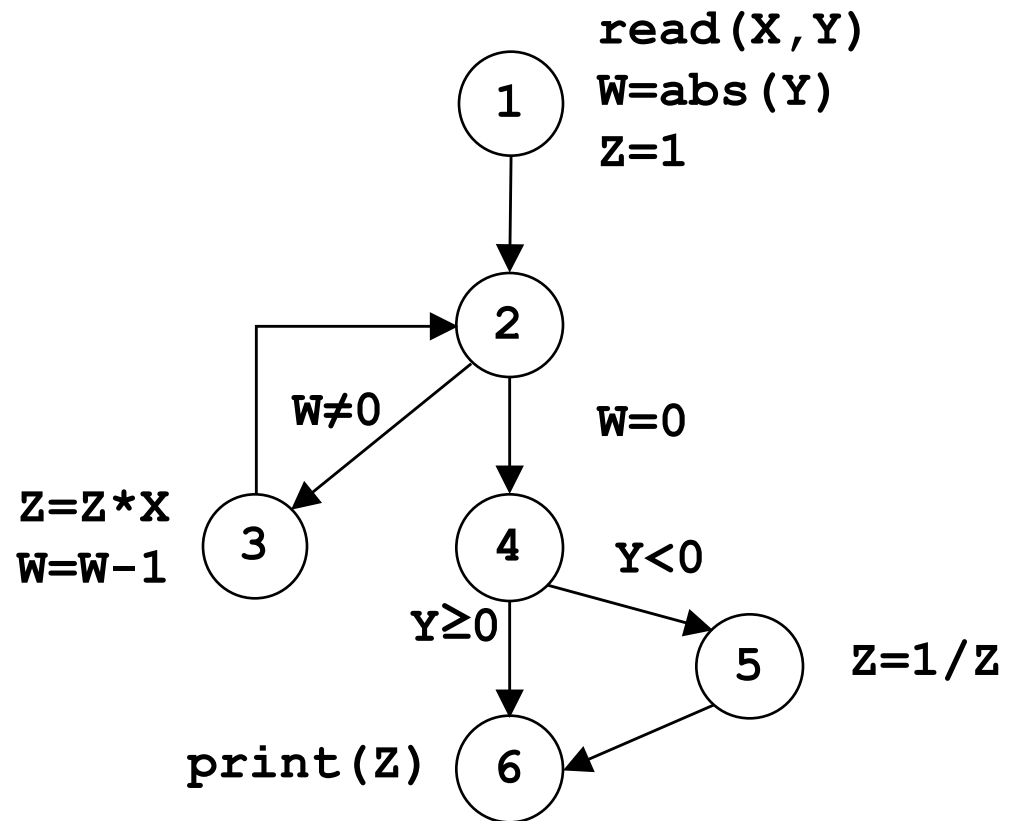

---

- ❑ Look for conditions that execute loops
  - Zero times
  - A maximum number of times
  - An average number of times (statistical criterion)
  
- ❑ For example, in the search algorithm
  - Skipping the loop
  - Executing the loop once or twice and then finding the element
  - Searching without finding the desired element

# Power Function Example

Program computing  $Z=X^Y$

```
BEGIN
  read (X, Y) ;
  W = abs(Y) ;
  Z = 1 ;
  WHILE (W <> 0) DO
    Z = Z * X ;
    W = W - 1 ;
  END
  IF (Y < 0) THEN
    Z = 1 / Z ;
  END
  print (Z) ;
END
```

# Power Function Example (cont.)

## □ All paths

### ➤ Infeasible path:

✓  $1 \rightarrow 2 \rightarrow 4 \rightarrow 5 \rightarrow 6$

### ➤ Infinite number of paths:

✓ As many ways to iterate

$2 \rightarrow (3 \rightarrow 2)^* \rightarrow 4 \rightarrow 5 \rightarrow 6$  as values of  $\text{abs}(Y)$

## □ All branches

### ➤ Two test cases are enough:

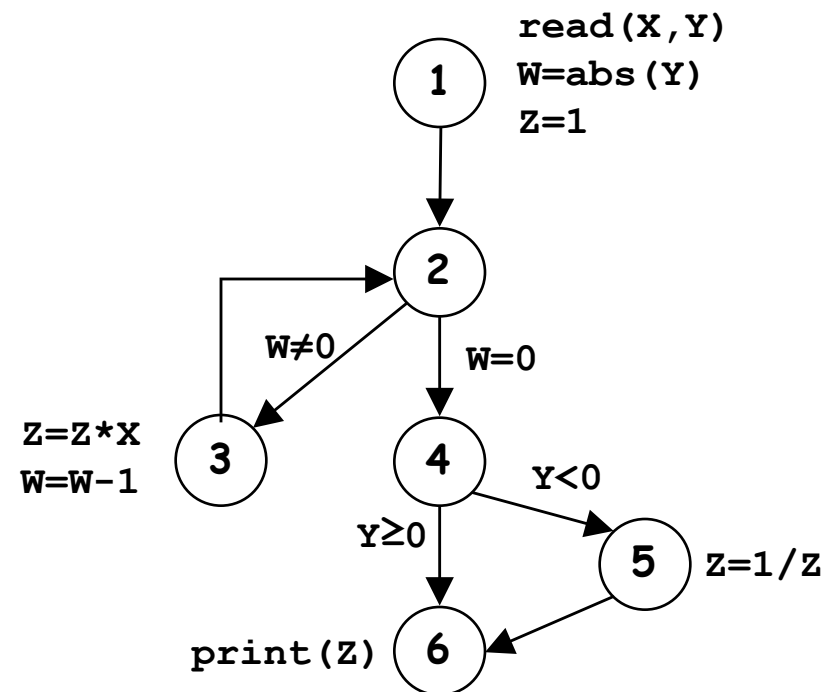

✓  $Y < 0 : 1 \rightarrow 2 \rightarrow (3 \rightarrow 2)^+ \rightarrow 4 \rightarrow 5 \rightarrow 6$

✓  $Y \geq 0 : 1 \rightarrow 2 \rightarrow (3 \rightarrow 2)^* \rightarrow 4 \rightarrow 6$

## □ All statements

### ➤ One test case is enough:

✓  $Y < 0 : 1 \rightarrow 2 \rightarrow (3 \rightarrow 2)^+ \rightarrow 4 \rightarrow 5 \rightarrow 6$

# Deriving Input Values

---

- ❑ Not all statements are reachable in real world programs
- ❑ It is not always possible to decide automatically if a statement is reachable and the percentage of reachable statements
- ❑ When one does not reach 100% coverage, it is therefore difficult to determine the reason
- ❑ Tools are needed to support this activity – and there exist good tools
- ❑ Research focuses on search algorithms to help automate coverage
- ❑ In general, control flow testing is, more applicable to testing in the small
